MACH1 / FleetLine E1 — Market Evidence Slides (Rebuilt)

Companion to `MACH1_MARKET_ASSESSMENT.md`. Keep the scenario labels visible wherever figures are used.

Slide 1 — Size the opportunity from observed rides

Headline: 591M annualized rides across three reported platforms; the E1 target pool is not yet directly measured.

Build

Reported daily platform rides	Daily rides	Source basis
Uber	840,000	Motilal Oswal figure cited by Business Standard, Apr 2025
Ola	460,000	Same source
Rapido	320,000	Same source; vehicle-class scope needs confirmation
Combined	**1.62M**	Sum of reported figures
Annualized	**591.3M**	×365; constant run-rate conversion

Formula / transparent scenarios

`Annual ride GMV = 591.3M rides × target-segment share × average realized target fare`

Scenario	Target share	Fare assumption	Illustrative annual GMV
Low	5%	₹300	**₹887 crore**
Central arithmetic case	10%	₹450	**₹2,661 crore**
High	15%	₹600	**₹5,322 crore**

Footnote: Scenario envelope, not an observed TAM or forecast. The daily ride figures are a press-cited analyst estimate; ₹300 is a broad all-cab reference, and share/fare bounds are assumptions. The target use cases overlap, so do not sum without trip-level de-duplication.
Speaker note: “We can show the arithmetic and the uncertainty. The next research step is to replace the target-share and target-fare assumptions with city/operator trip evidence.”

Slide 2 — What current evidence can answer

Headline: Registrations tell us what vehicles enter the market; trips tell us what fleets need.

Evidence source	Answers	Does not answer
VAHAN / Autiqa Lens Pro	State, OEM, model, fuel, registration trends; seasonal mix; competitive share	Taxi-purpose share, fares, active fleet, paid km, driver/operator margin
AutoPunditz wholesale data	OEM/model dispatch trends, launches, powertrain competition	Retail registrations or taxi purchases without reconciliation
Platform/operator trips	Use case, fare, utilization, deadhead, cancellations, city demand	National market unless coverage is weighted and expanded
Rider MaxDiff/conjoint	Attribute trade-offs and preference segments	Actual fleet economics or vehicle purchase conversion

Research choices

- **Forecast registrations:** seasonal-naive baseline vs ETS/Holt–Winters, rolling backtest; report error and scope.
- **Estimate EV adoption effects:** city/state monthly panel; fixed effects or DiD only when policy exposure, comparison groups, and pre-trends are credible.
- **Group demand types:** observed city × use-case cells, exploratory hierarchical clustering with scaling/linkage/resampling checks.
- **Choose vehicle configuration:** evidence-backed weighted decision matrix; show weight sensitivity.

Speaker note: “We do not have a sample for segmentation or regression yet. We are separating supply-side data from demand-side data before making a causal or product-fit claim.”

Slide 3 — The decision still to validate

Headline: Test where E1 economics work before calling a segment the winner.

Required operator evidence

1. Paid and total km per shift, including empty return/deadhead.
2. Completed trips, fare distribution, trip purpose, booking channel, and city.
3. Energy/fuel, maintenance, charging/refuelling downtime, uptime, and airport fees.
4. Vehicle price/finance, insurance, warranty, taxes, residual value, and replacement cycle.
5. Contract terms: operator take, driver take, commission/subscription, minimum utilization.

Vehicle-market evidence to pair with it

- Lens Pro / VAHAN: model, fuel, geography, and month registration panels, with consistent national denominators.
- AutoPunditz: monthly OEM/model wholesale panel; keep wholesale and retail series distinct.
- Fleet purchases / permits: identify active commercial vehicles and replacement rather than treating every registration as a taxi.

Conclusion: Airport, corporate, commute, city, premium, and intercity are overlapping dimensions. Until trip and operator data are obtained, E1's target and duty-cycle fit remain hypotheses, not findings.
